## Definition

A finite automaton is 5-tuple  $(Q, \Sigma, \delta, q_0, F)$  where:

1.  $Q$  is a finite set called the states
2.  $\Sigma$  is a finite set called the alphabet
3.  $\delta : Q \times \Sigma \rightarrow Q$  is the transition function
4.  $q_0 \in Q$  is the start state
5.  $F \subseteq Q$  is the set of accept states

# DFA Computation

Now we formalise finite automaton's computation as follows: Let  $M = (Q, \Sigma, \delta, q_o, F)$  be a finite automaton and let  $w = w_1 w_2 \dots w_n$  be a string where each  $w_i$  is a member of  $\Sigma$ .

## Definition

Then  $M$  **accepts**  $w$  if a sequence of states  $r_0, r_1, \dots, r_n$  in  $Q$  exists with three conditions:

1.  $r_0 = q_o$
2.  $\delta(r_i, w_{i+1}) = r_{i+1}$ , for  $i = 0, \dots, n - 1$
3.  $r_n \in F$

# Regular Language

## Definition

A language is called a regular language if some finite automaton recognizes it.

# Regular operations

## Definition

Let  $A$  and  $B$  be languages. We define the regular operations **union**, **concatenation**, and **star** as follows:

- Union:  $A \cup B = \{x \mid x \in A \text{ or } x \in B\}$
- Concatenation:  $A \circ B = \{xy \mid x \in A \text{ and } y \in B\}$
- Star:  $A^* = \{x_1x_2 \dots x_k \mid k \geq 0 \text{ and each } x_i \in A\}$

## empty string

empty string  $\epsilon$  is always a member of  $A^*$ , no matter what  $A$  is.

# Closure under union

## Theorem

*The class of regular languages is closed under the union operation, meaning that if  $A_1$  and  $A_2$  are regular languages, so is  $A_1 \cup A_2$ .*

# Closure under union

Proof idea:

- Because  $A_1$  and  $A_2$  are regular, we know that some finite automaton  $M_1$  recognizes  $A_1$  and some finite automaton  $M_2$  recognizes  $A_2$
- To prove  $A_1 \cup A_2$  is regular we need a finite automaton called  $M$  that recognize  $A_1 \cup A_2$ . This is a proof by **construction**
- This FA  $M$  must accept an input string if either  $M_1$  or  $M_2$  accepts it. So we simulate somehow  $M_1$  and  $M_2$
- Cannot be done in sequential order because once a symbol has been read then it is gone
- So we simulate  $M_1$  and  $M_2$  simultaneously by remembering the pair of states
- If size (i.e., number of states) of  $M_1$  is  $k_1$  and size of  $M_2$  is  $k_2$  then we have  $k_1 \times k_2$  pairs

# Generalization of determinism

- So far in our discussion, every step of a computation follows in a unique way from the preceding step
- When the machine is in a given state and reads the next input symbol, we know what the next state will be
- We call this a **deterministic** computation
- In a more general approach, a **nondeterministic** machine has several choices for the next state at any point
- Since it is a generalization it means that every deterministic finite automaton (**DFA**) is automatically a nondeterministic finite automaton (**NFA**)

## Section 3

### Nondeterminism

# Generalization of determinism

Figure: The nondeterministic finite automaton  $N_1$

# Differences between NFA and DFA

- While a DFA always has exactly one exiting transition arrow, an NFA may have zero, one, or many exiting arrows for each alphabet symbol
- in a DFA, labels on the transition arrows are symbols from the alphabet, while an NFA can have the  $\epsilon$  label.

# How does an NFA compute

- When reading a symbol and there is only one way to proceed we have the DFA situation
- When reading a symbol and there are many ways to proceed (multiple arrows with the same symbol) the machine splits into multiple copies of itself and follows all the possibilities in parallel.
- If a state with an  $\epsilon$  symbol on an exiting arrow is encountered, without reading any input, the machine splits into multiple copies (following each  $\epsilon$  labeled arrow)

# Intuition 1

Nondeterminism may be viewed as a kind of **parallel computation** wherein multiple independent “processes” or “threads” can be running concurrently.

When the NFA splits to follow several choices, that corresponds to a process “forking” into several children, each proceeding separately. If at least one of these processes accepts, then the entire computation accepts.

## Intuition 2

Another way to think of a nondeterministic computation is as a **tree of possibilities**.

The root of the tree corresponds to the start of the computation. Every branching point in the tree corresponds to a point in the computation at which the machine has multiple choices. The machine accepts if at least one of the computation branches ends in an accept state

# Intuition 2

Deterministic  
computation

Nondeterministic  
computation

Figure: Deterministic and nondeterministic computations with an accepting branch

# Why bother with NFAs?

NFA are useful in several respects:

- constructing NFAs is sometimes easier than directly constructing DFA because they are much smaller
- Every NFA can be converted into an equivalent DFA
- NFAs is a good introduction to nondeterminism in more powerful computational models because they are easy to understand

# Example

Figure:  $N_1$  NFA

Figure: The computation of  $N_1$  on input 010110

# Example

Let  $A$  be the language consisting of all strings over  $\{0, 1\}$  containing 1 in the third position from the end (e.g., 000100 is in  $A$  but 0011 is not)

Figure: The NFA  $N_2$  recognizing  $A$

# Example

Figure: The DFA  $M_2$  recognizing  $A$

# Example

Let  $A$  be the language consisting of all strings over  $\{0\}$  having the form  $0^k$  where  $k$  is a multiple of 2 or 3 (e.g.,  $\epsilon$ , 00, 000, 000000 but not 0 or 00000)

Figure: The NFA  $N_3$  recognizing  $A$

# Example

Figure: The NFA  $N_4$  recognizing  $A$

Does  $N_4$  accepts  $\epsilon$ ,  $a$ ,  $baba$ ? Does it accepts  $bb$ ?

# Formal definition

- The formal definition of a nondeterministic finite automaton is similar to that of a deterministic finite automaton.
- However, transition function is the key difference

# Formal definition

## Definition

A nondeterministic finite automaton is a 5-tuple  $(Q, \Sigma, \delta, q_0, F)$ , where

1.  $Q$  is a finite set of states
2.  $\Sigma$  is a finite alphabet
3.  $\delta : Q \times \Sigma_\epsilon \rightarrow \mathcal{P}(Q)$  is the transition function
4.  $q_0 \in Q$  is the start state
5.  $F \subseteq Q$  is the set of accepted states

We denote  $\Sigma_\epsilon = \Sigma \cup \{\epsilon\}$  and  $\mathcal{P}(Q)$  as the power set of  $Q$ .

# Example

Figure: The NFA  $N_1$

Formal description of  $N_1$  is  $(Q, \Sigma, \delta, q_1, F)$  where:

1.  $Q = \{q_1, q_2, q_3, q_4\}$
2.  $\Sigma = \{0, 1\}$
3.  $\delta$  is given as

	0	1	$\epsilon$
$q_1$	$\{q_1\}$	$\{q_1, q_2\}$	$\emptyset$
$q_2$	$\{q_3\}$	$\emptyset$	$\{q_3\}$
$q_3$	$\emptyset$	$\{q_4\}$	$\emptyset$
$q_4$	$\{q_4\}$	$\{q_4\}$	$\emptyset$

4.  $q_1$  is the start state
5.  $F = \{q_4\}$

# Formal definition

Now we formalise NFA's computation as follows:

## Definition

Let  $N = (Q, \Sigma, \delta, q_0, F)$  be a NFA and  $w$  a string over alphabet  $\Sigma$ . Then we say that  $N$  **accepts**  $w$  if we can write  $w$  as  $w = y_1 y_2 \dots y_m$  where each  $y_i$  is a member of  $\Sigma_\epsilon$  and a sequence of states  $r_0, r_1, \dots, r_m$  exists in  $Q$  with three conditions:

1.  $r_0 = q_0$
2.  $r_{i+1} \in \delta(r_i, y_{i+1})$ , for  $i = 0, \dots, m - 1$
3.  $r_m \in F$

Observe that  $\delta(r_i, y_{i+1})$  is a set of allowable next states.

## Section 4

### Equivalence of NFAs and DFAs

# Equivalence of NFAs and DFAs

- NFAs appear to have more power than DFAs, so we might expect that NFAs recognize more languages.
- But deterministic and nondeterministic finite automata recognize the same class of languages
- This is important because describing an NFA for a given language sometimes is much easier than describing a DFA for that language

## Definition

Two machines are equivalent if they recognize the same language

# Equivalence of NFAs and DFAs

## Theorem

*Every NFA has an equivalent DFA.*

Proof idea:

- The idea is to convert the NFA into an equivalent DFA that **simulates** the NFA.
- In the examples of NFAs we kept track of the various branches of the computation
- If  $k$  is the number of states of the NFA, it has  $2^k$  subsets of states
- So the DFA simulating the NFA will have  $2^k$  states
- Now we need to figure out which will be the start state and accept states of the DFA, and what will be its transition function

# Equivalence of NFAs and DFAs I

## Theorem

*Every NFA has an equivalent DFA.*

# Equivalence of NFAs and DFAs II

## Proof.

Let  $N = (Q, \Sigma, \delta, q_0, F)$  be a NFA. We construct a DFA  $M = (Q', \Sigma, \delta', q'_0, F')$  recognizing  $A$ . First we do our construction on an easy case when  $N$  has no  $\epsilon$  arrows.

1.  $Q' = \mathcal{P}(Q)$ . Every state of  $M$  is a set of states of  $N$ .
2. For  $R \in Q'$  and  $a \in \Sigma$ , let  $\delta'(R, a) = \{q \in Q \mid q \in \delta(r, a) \text{ for some } r \in R\}$ . If  $R$  is a state of  $M$ , it is also a set of states of  $N$ . When  $M$  reads symbol  $a$  in state  $R$  it shows where  $a$  takes each state on  $R$ . Because each state can go to a set of states we take the union of all these sets. More concisely:

$$\delta'(R, a) = \bigcup_{r \in R} \delta(r, a)$$

3.  $q'_0 = \{q_0\}$ .  $M$  starts in the state corresponding to the collection containing just the start state of  $N$ .
4.  $F' = \{R \in Q' \mid R \text{ contains an accept state of } N\}$ . The machine  $M$  accepts if one of the possible states that  $N$  could be in at this point is an accept state.

# Equivalence of NFAs and DFAs

Now we need to consider the  $\epsilon$  arrows. For this we define:

$$E(R) = \{q \mid q \text{ can be reached from } R \text{ by traveling along 0 or more } \epsilon \text{ arrows}\}$$

All we have to do now is to modify the transition function of  $M$  so that we can reach the states when also going along  $\epsilon$  arrows:

$$\delta'(R, a) = \{q \in Q \mid q \in E(\delta(r, a)) \text{ for some } r \in R\}$$

Additionally, we need to modify the start state of  $M$  to visit all possible states that can be reached from the start state of  $N$  along the  $\epsilon$  arrows. So  $q'_0 = E(\{q_0\})$

# Equivalence of NFAs and DFAs

## Corollary

*A language is regular if and only if some nondeterministic finite automaton recognizes it.*

## Proof.

Hint:  $\Leftrightarrow$  type of proof. We use the above theorem and another one from the previous lecture

# Example

Figure:  $N_4$  NFA

Let's convert the the following NFA  
 $N_4 = (\{1, 2, 3\}, \{a, b\}, \delta, 1, \{1\})$  to a DFA named  $M$ .

# Example

Figure:  $N_4$  NFA

- First we need to determine  $M$ 's states.
- Since  $N_4$  has three states,  $\{1, 2, 3\}$ , we get eight states:

$$M = \{\emptyset, \{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1, 2, 3\}\}$$

# Example

Figure:  $N_4$  NFA

- Next, we determine the start and accept states of  $M$ .
- The start state is  $E(\{1\})$ , the set of states that are reachable from 1 by traveling along  $\epsilon$  arrows, plus 1 itself. An  $\epsilon$  arrow goes from 1 to 3, so  $E(\{1\}) = \{1, 3\}$ .
- The accept states are those containing  $N_4$ 's accept state:  $\{\{1\}, \{1, 2\}, \{1, 3\}, \{1, 2, 3\}\}$

# Example

Figure:  $N_4$  NFA

- At last, we determine  $M$ 's transition function.
- In  $M$  state  $\{2\}$  goes to  $\{2, 3\}$  on input  $a$ . State  $\{2\}$  goes on state  $\{3\}$  on input  $b$
- State  $\{1\}$  goes on  $\emptyset$  because no  $a$  arrows
- State  $\{1, 2\}$  goes to  $\{2, 3\}$  because 2 points to both 2 and 3 on  $M$

# Example

Figure:  $M$  DFA corresponding to NFA  $N_4$

# Example

Figure: DFA  $M$  after removing unnecessary states
